Heterogeneity in Consumers’ learning about Inflation

Discussion

Adeline Delavande

RAND Corporation and Universidade Nova de Lisboa
Objectives of the study

- Evaluate how accuracy of one-year ahead inflation expectation differs from first interview versus second interview 6 months later

- Evaluate whether this difference varies systematically with observable characteristics

- Data from Michigan Survey of Consumer Attitudes and Behavior Series between 1983 and 1996
  - By about what percent do you expect prices to go (up/down) on the average during the next 12 months?
    - No information on uncertainty about inflation
  - Short rotating panel: 40% of respondents are re-contacted 6 months after first interview
Findings

● Forecast error (measured by the absolute value of the difference between one-year ahead expectations and realized inflation) is lower at re-interview
  ● By 0.5 percentage point on average

● Heterogeneity in how forecast improves
  ● E.g., low income individuals improve their forecast more than middle income individual
  ● Younger individuals (<34) improve their forecast more than those aged 34-55

● Individuals who are the least accurate at first interview tend to improve more
  ● Less heterogeneity in expectations at second interview
Implications

- Caution when using the inflation expectations data
  - In any given month, 40% of the sample is re-interviewed
- Accuracy of inflation forecast can be changed
- Evidence consistent with adaptive learning
  - Agents potentially learn from their forecast error and improve their forecast over time
What could generate lower forecast error at second interview?

- Selective attrition?
  - Respondents with more accurate expectations are more likely to be re-interviewed
  - Authors take into account attrition
What could generate lower forecast error at second interview?

- Adaptive learning / change in “forecasting equation”?
  - This would mean that only respondents who are interviewed make inflation forecast and learn from their mistakes
  - If inflations expectations are important for decision-making, most individuals should have expectations about inflations, and could learn from observing inflation realizations
What could generate lower forecast error at second interview?

- Change in information set (potentially combined with adaptive learning)?
  - Less heterogeneity in second interview due to more similar information set
  - Being asked about inflation in a survey may increase attention toward information related to inflation so difference in information set between the two waves of interview may be smaller across respondents
  - Do they pay more attention to news/announcement about inflation?
  - Do they pay more attention to price changes?

- Maybe attention toward information leads respondents to also change their forecasting rules
Why does a survey question lead to (potentially) more attention?

- Do respondents know that they will be re-interviewed?
  - Want to perform “better” at second interview

- Do respondents want to improve their forecast for decision-making?
Implication from policies

- Good news: Limited intervention (one survey question) helps improve accuracy of inflation forecast

- What can be done to increase awareness / attention of consumers?
  - Depends on what individuals focus to make forecast?
Can we learn more from the long panel?
