

OIL PRICE DYNAMICS REPORT

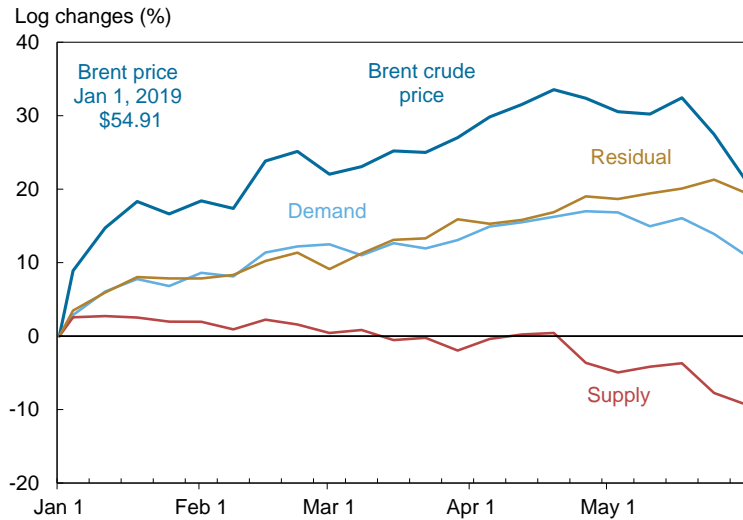

Updated: June 3, 2019

Oil prices fell this week owing to decreased demand and higher supply.

- Lower demand expectations and higher anticipated supply resulted in lower oil prices this week. In 2019:Q1, oil prices rose due to increasing demand.
- In 2018, strengthening global demand expectations drove oil prices higher. This trend reversed in 2018:Q4, when weaker expected demand and higher anticipated supply lowered prices.
- Overall, between 2014 and 2017, both lower global demand expectations and higher anticipated supply held oil prices down. Since mid-2017, this trend has reversed as stronger demand expectations and stabilizing anticipated supply have driven oil prices higher.

Our analysis of oil price movements does not necessarily represent the views of the Federal Reserve Bank of New York, the Federal Reserve System, or the Federal Open Market Committee.

Recent Decomposition Data

- The chart at left depicts the cumulative oil price decomposition from January 1, 2019.
- The table below presents the most recent cumulative values.

Cumulative Percentage Changes since January 1, 2019

	Demand	Supply	Rest	Brent
May 17, 2019	16.1	-3.7	20.1	32.4
May 24, 2019	13.9	-7.8	21.3	27.5
May 31, 2019	11.0	-9.3	19.5	21.1

Longer-Term View of Oil Price Movements

- This final chart provides a somewhat longer-term perspective by means of a cumulative decomposition from 2010 onward.
- The analysis shows that excess supply became a significant driver of oil prices in mid-2012 and generally dominated price dynamics after mid-2014.

Oil Price Decomposition Q&A

1. What is the goal of the oil price decomposition?

Our aim is to determine how much of the observed oil price change has been driven by demand and supply factors.

2. What is the modeling strategy?

Using a statistical model and a large number of financial variables, we decompose weekly oil price changes into demand effects, supply effects, and an unexplained residual.

Sparse partial least squares regression allows us to construct linear combinations from the variables in our financial market data set—called factors—which have maximum explanatory content for oil price changes. We first use this procedure to generate factors that best capture the patterns in the data, and then examine the estimated factors to determine how they reflect demand or supply dynamics.

The model is re-estimated every week using weekly data from January 1986 through the close of business on Friday of the most recent week. Over this sample, the model can explain about two-thirds of the weekly oil price dynamics.

3. How to interpret the results?

The output of the model is used to decompose weekly changes in an accounting sense. More specifically, the weekly Brent crude price change always equals the change explained by demand factors plus the change explained by supply factors plus a residual (the weekly change unexplained by the sum of the estimated demand and supply factors).

Given the noise in weekly price changes, we choose to show the results as a cumulation from a certain starting point (usually the start of the previous quarter).
